## Dimensionality Reduction

Nakul Verma

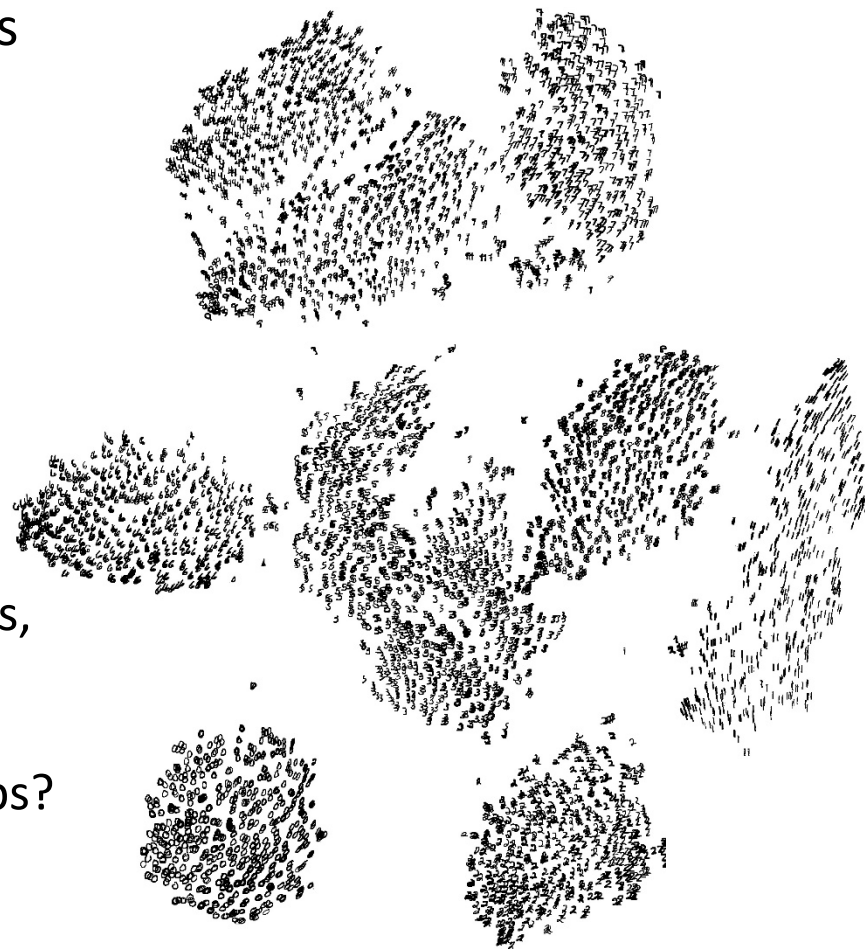

# Example: Handwritten digits

Handwritten digit data, but with no labels

0 1 2 3 4 5 6 7 8 9  
0 1 2 3 4 5 6 7 8 9  
0 1 2 3 4 5 6 7 8 9  
0 1 2 3 4 5 6 7 8 9  
0 1 2 3 4 5 6 7 8 9

What can we do?

- Suppose know that there are 10 groupings, can we find the groups?
- What if we don't know there are 10 groups?
- How can we discover/explore other structure in such data?

**A 2D visualization of digits dataset**

# Dimensionality Reduction

Data:  $\vec{x}_1, \vec{x}_2, \dots, \vec{x}_n \in \mathbf{R}^d$

Goal: find a ‘useful’ transformation  $\phi : \mathbf{R}^d \rightarrow \mathbf{R}^k$  that helps in the downstream prediction task.

Some previously seen useful transformations:

- z-scoring  $(x_1, \dots, x_d) \mapsto \left( \frac{x_1 - \mu_1}{\sigma_1}, \dots, \frac{x_d - \mu_d}{\sigma_d} \right)$

*Keeps same dimensionality  
but with better scaling*

- Kernel transformations.

*Higher dimensionality,  
making data linearly separable*

**What are other desirable feature transformations?**

*How about lower dimensionality while keeping the relevant information?*

# Principal Components Analysis (PCA)

Data:  $\vec{x}_1, \vec{x}_2, \dots, \vec{x}_n \in \mathbf{R}^d$

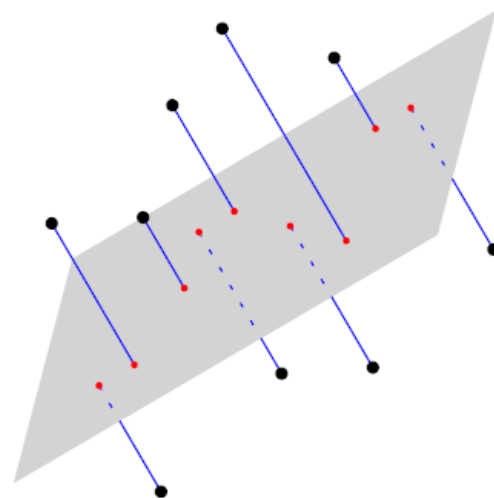

Goal: find the best **linear** transformation  $\phi : \mathbf{R}^d \rightarrow \mathbf{R}^k$  that best maintains reconstruction accuracy.

*Equivalently, minimize aggregate residual error*

Define:  $\Pi^k : \mathbf{R}^d \rightarrow \mathbf{R}^d$  *k-dimensional orthogonal linear projector*

$$\underset{\Pi^k}{\text{minimize}} \quad \frac{1}{n} \sum_{i=1}^n \left\| \vec{x}_i - \Pi^k(\vec{x}_i) \right\|^2$$

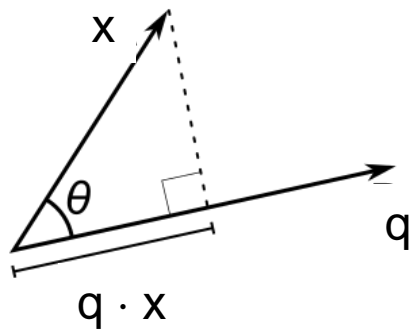

*How do we optimize this?*

# Dimensionality Reduction via Projections

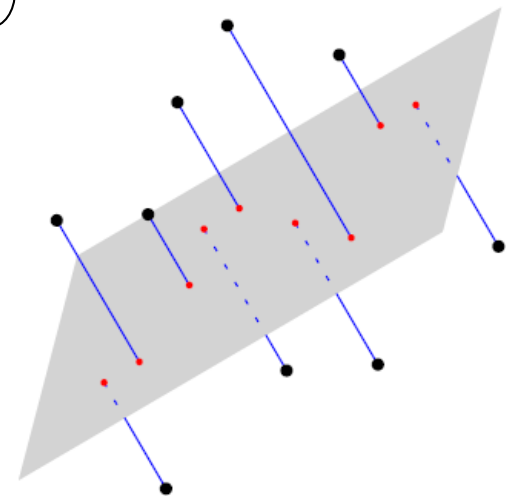

A  $k$  dimensional subspace can be represented by  $\vec{q}_1, \dots, \vec{q}_k \in \mathbf{R}^d$  orthonormal vectors.

The projection of any  $\vec{x} \in \mathbf{R}^d$  in the  $\text{span}(\vec{q}_1, \dots, \vec{q}_k)$  is given by

$$\sum_{i=1}^k (\vec{q}_i \cdot \vec{x}) \vec{q}_i = \underbrace{\left( \sum_{i=1}^k \vec{q}_i \vec{q}_i^T \right)}_{\Pi^k} \vec{x}$$

To represent it in  $\mathbf{R}^k$  (using basis  $\vec{q}_1, \dots, \vec{q}_k$ ) the coefficients simply are:  $(\vec{q}_1 \cdot \vec{x}), \dots, (\vec{q}_k \cdot \vec{x})$

# PCA: $k = 1$ case

If projection dimension  $k = 1$ , then looking for a  $q$  such that

$$\text{minimize}_{\|q\|=1} \quad \frac{1}{n} \sum_{i=1}^n \left\| \vec{x}_i - (\vec{q} \vec{q}^\top) \vec{x}_i \right\|^2$$

$$\begin{aligned} \frac{1}{n} \sum_{i=1}^n \left\| \vec{x}_i - (\vec{q} \vec{q}^\top) \vec{x}_i \right\|^2 &= \left( \frac{1}{n} \sum_{i=1}^n \vec{x}_i^\top \vec{x}_i \right) - \vec{q}^\top \left( \frac{1}{n} \sum_{i=1}^n \vec{x}_i \vec{x}_i^\top \right) \vec{q} \\ &\propto - \vec{q}^\top \left( \frac{1}{n} X X^\top \right) \vec{q} \end{aligned}$$

Equivalent formulation:

$$\text{maximize}_{\|q\|=1} \quad \vec{q}^\top \left( \frac{1}{n} X X^\top \right) \vec{q}$$

*How to solve?*

# Eigenvectors and Eigenvalues

Recall for any matrix  $M$ , the  $(\lambda, v)$  pairs of the fixed point equation

$$Mv = \lambda v$$

are the eigenvalue and the eigenvectors of  $M$ . ( $v \neq 0$ )

$$v^T M v = \lambda v^T v$$

$$\lambda = \frac{v^T M v}{v^T v} = \bar{v}^T M \bar{v} \quad \text{where } \bar{v} = \frac{v}{\|v\|} \quad (\text{ie, unit length})$$

So,

$$\text{maximize}_{\|q\|=1} \quad \vec{q}^T \left( \frac{1}{n} X X^T \right) \vec{q}$$

**Basically is the top eigenvector  
of matrix  $(1/n) X X^T$ !**

# PCA: $k = 1$ case

$$\text{maximize}_{\|\vec{q}\|=1} \vec{q}^\top \left( \frac{1}{n} X X^\top \right) \vec{q}$$

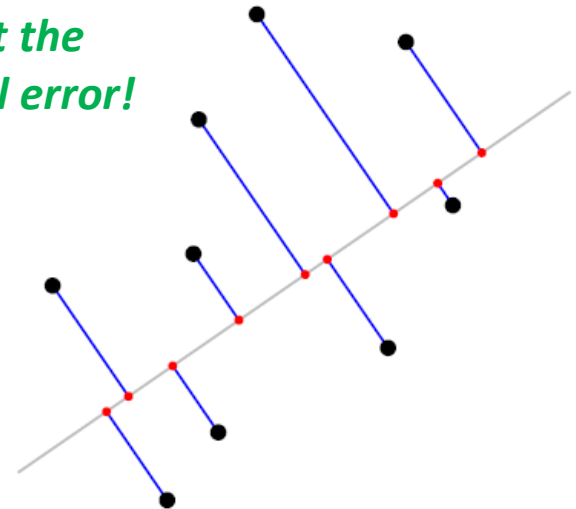

Covariance of data (if mean = 0)

For any  $q$  the quadratic form  $\vec{q}^\top \left( \frac{1}{n} X X^\top \right) \vec{q}$  is the empirical

variance of data in the direction  $q$ , ie, of data  $\vec{q}^\top \vec{x}_1, \dots, \vec{q}^\top \vec{x}_n$  *why?*

*Therefore, the top eigenvector solution implies that the direction of maximum variance minimizes the residual error!*

*What about general  $k$ ?*

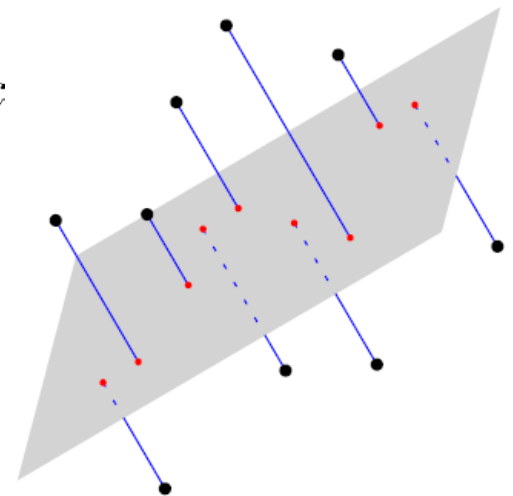

# PCA: general $k$ case

$$\arg \min_{\substack{Q \in \mathbf{R}^{d \times k} \\ Q^T Q = I}} \frac{1}{n} \sum_{i=1}^n \|\vec{x}_i - QQ^T \vec{x}_i\|^2 = \arg \max_{\substack{Q \in \mathbf{R}^{d \times k} \\ Q^T Q = I}} \text{tr} \left( Q^T \left( \frac{1}{n} X X^T \right) Q \right)$$

*Solution: Basically is the top  $k$  eigenvectors of the matrix  $XX^T$  !*

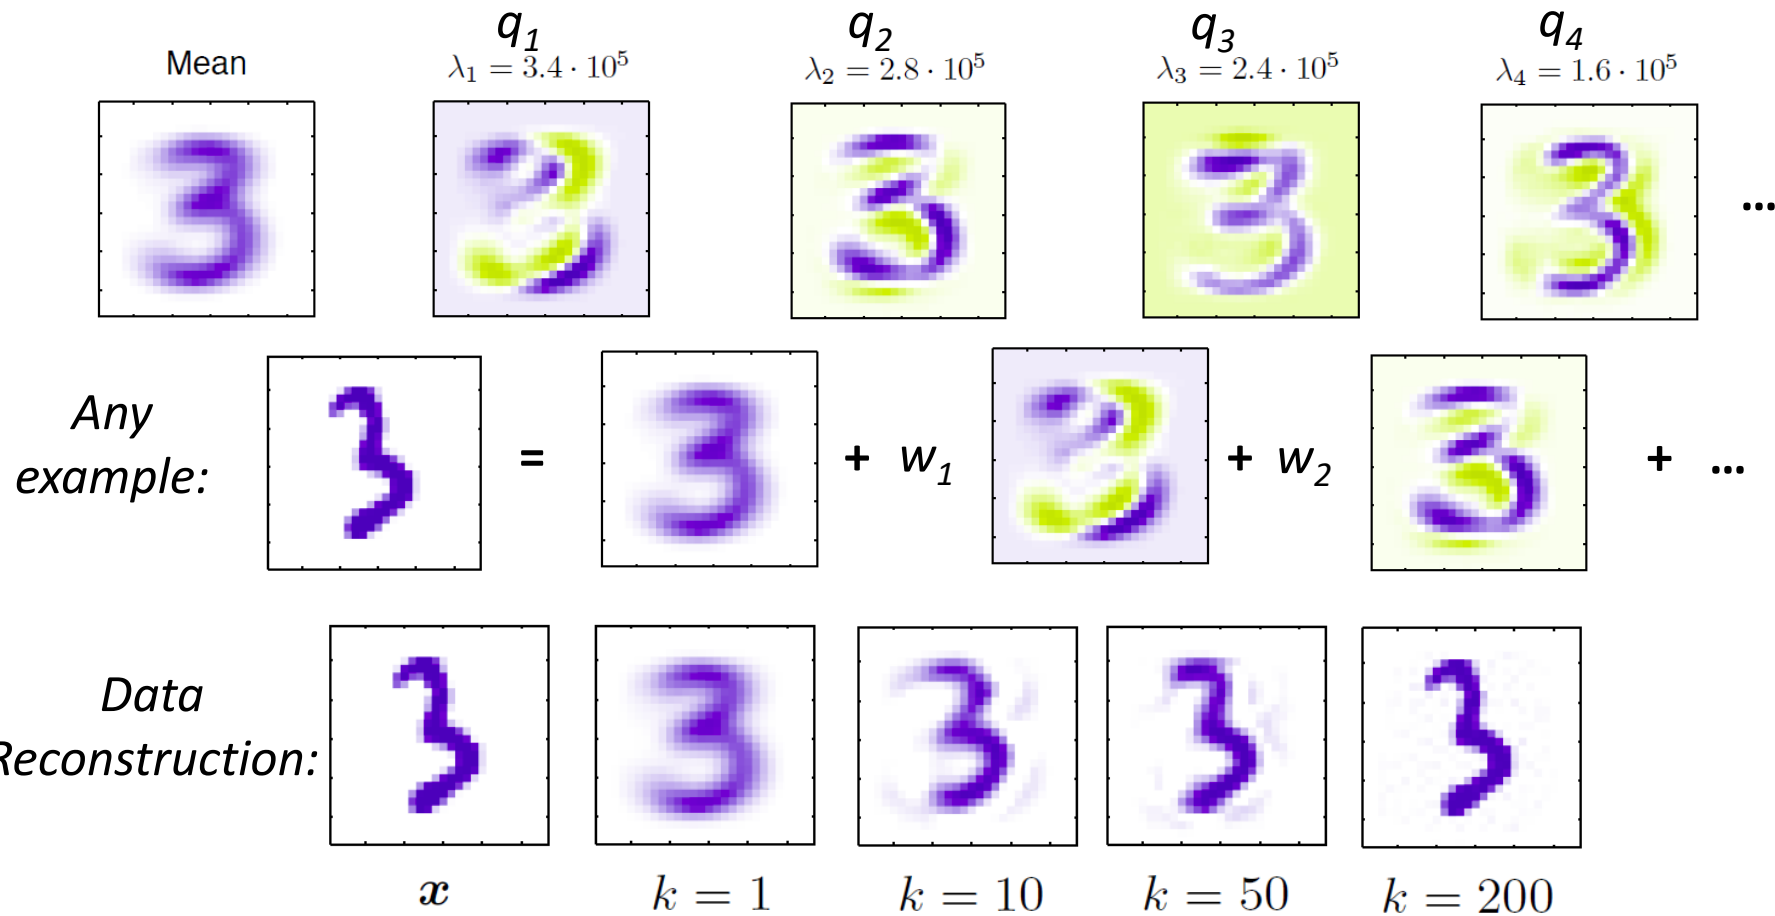

$$\text{tr} \left( Q^T \left( \frac{1}{n} X X^T \right) Q \right) = \sum_{i=1}^k \text{empirical variance of } \vec{q}_i^T x$$

***$k$ -dimensional subspace preserving maximum amount of variance***

# PCA: Example Handwritten Digits

*Images of handwritten 3s in  $\mathbf{R}^{784}$*

***We can compress the each datapoint to just  $k$  numbers!***

# Other Popular Dimension Reduction Methods

Multi-dimensional Scaling

Independent Component Analysis (ICA) (for blind source separation)

Non-negative matrix factorization (to create additive models)

Dictionary Learning

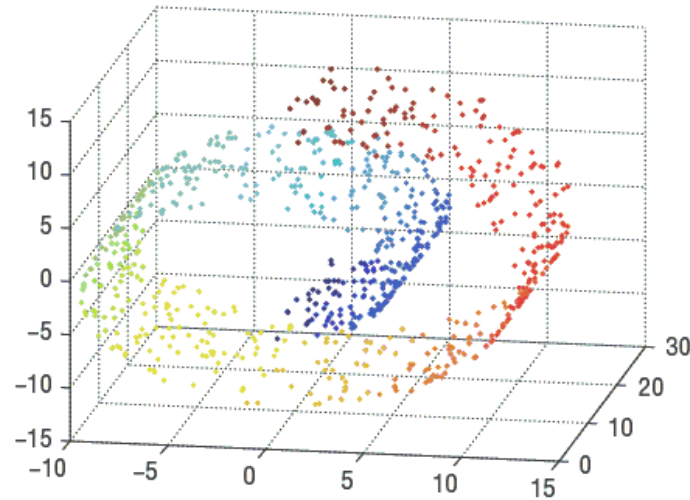

Random Projections

...

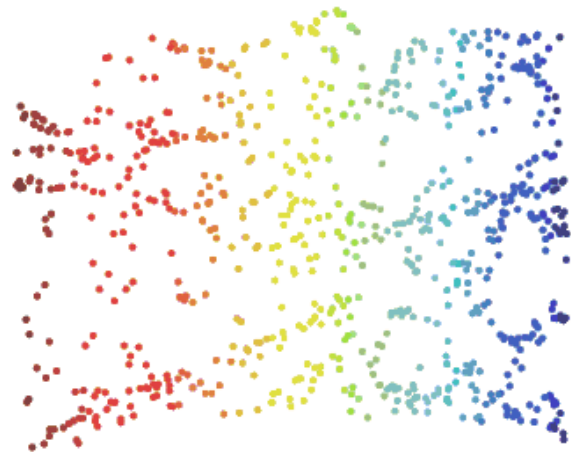

*All of them are **linear** methods*

# Non-Linear Dimensionality Reduction

Consider non-linear data

*Linear embedding*

*non-linear embedding*

# Non-Linear Dimensionality Reduction

Basic optimization criterion:

Find an embedding that:

- Keeps neighboring points close
- Keeps far-off points far

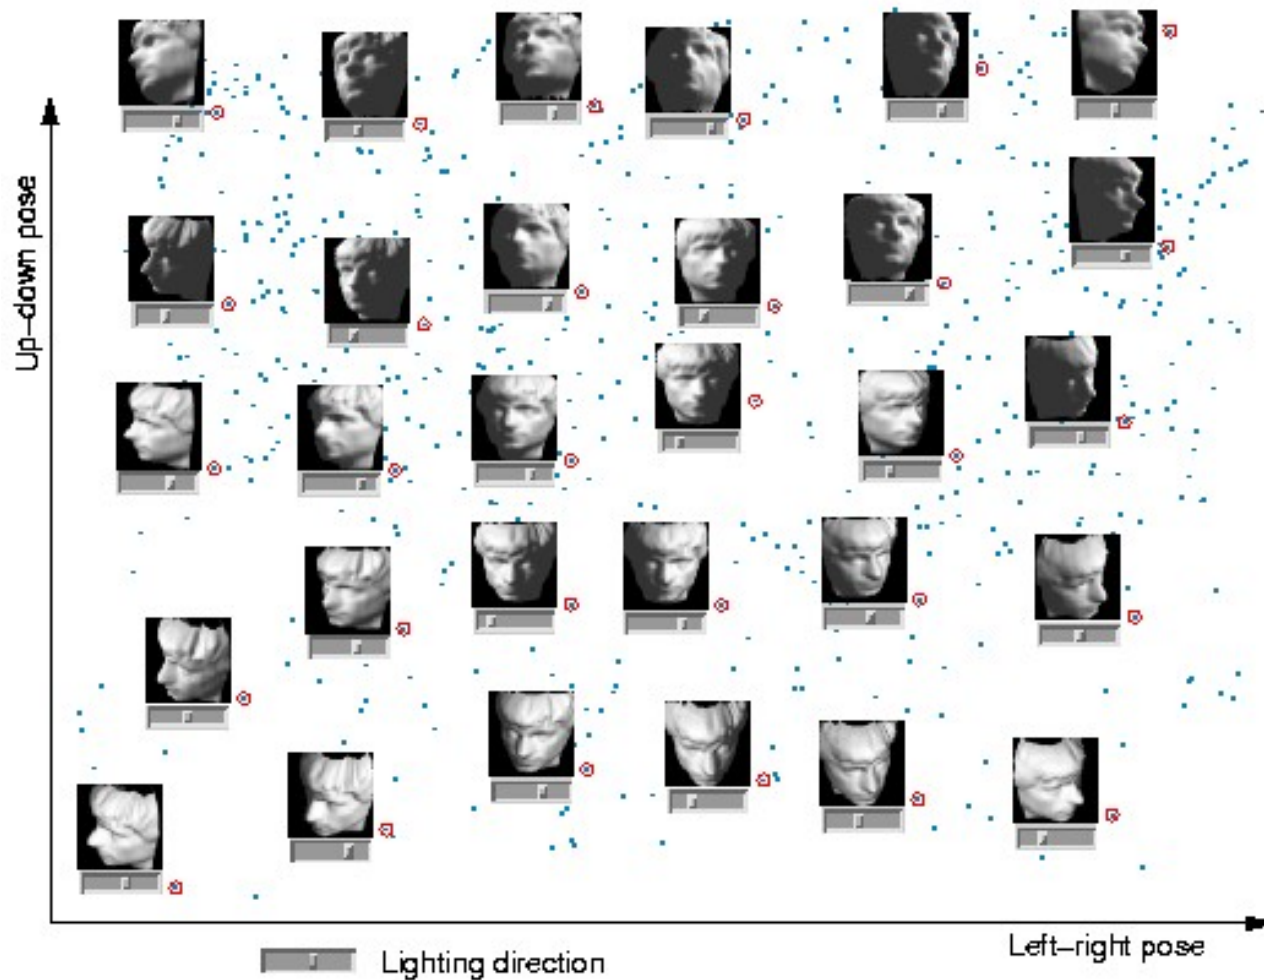

*Example variation 1:*

*Distort neighboring distances by at most  $(1 \pm \varepsilon)$  factor, while maximizing non-neighbor distances.*

*Example variation 2:*

*Compute **geodesic** (local hop) distances, and find an embedding that best preserves geodesics.*

# Non-linear embedding: Example

# Popular Non-Linear Methods

Locally Linear Embedding (LLE)

Isometric Mapping (IsoMap)

Laplacian Eigenmaps (LE)

Local Tangent Space Alignment (LTSA)

Maximum Variance Unfolding (MVU)
